Abstract
In this paper, we consider the electrical impedance tomography problem in a computational approach. This inverse problem is the recovery of the electrical conductivity $\sigma$ in a domain from boundary measurements, given in the form of the Neumann-to-Dirichlet map. We formulate the inverse problem as a variational one, with a fitting term and a regularization term. We restrict the minimization with respect to the unknown $\sigma$ to piecewise-constant functions defined on rectangular domains in two dimensions. We borrow image segmentation techniques to solve the minimization problem. Several experimental results of conductivity reconstruction from synthetic data are shown, with and without noise, that validate the proposed method.

1 The mathematical problem
Electrical Impedance Tomography (EIT) is a non-invasive inverse method which attempts to determine the electrical conductivity $\sigma$ of a medium in a domain $\Omega$, by making voltage and current measurements at the boundary, $\partial\Omega$, of the medium. In mathematical terms, the EIT problem is the recovery of the coefficient $\sigma$ of an elliptic partial differential equation, defined for $x \in \Omega$, given knowledge of the Cauchy data, i.e. the Neumann-to-Dirichlet map or the Dirichlet-to-Neumann map. The EIT problem has important applications in fields such as medical imaging, non-destructive testing of materials, environmental cleaning, geophysics, etc. In the

last two decades, it has been the topic of many theoretical and numerical studies. However, there are still important questions, such as improving the stability of reconstruction algorithms, improving the resolution and reliability of reconstructions of \( \sigma \), and increasing the speed of inversion algorithms so \( \sigma \) can be imaged in real time [3].

1.1 The Forward Problem

For a known isotropic electrical conductivity function \( \sigma \in L^\infty(\Omega) \) (scalar valued, strictly positive and bounded in \( \Omega \)), we can define the Neumann-to-Dirichlet map, \( \Lambda_\sigma \), for a bounded and simply connected domain \( \Omega \) in the following way. Let \( u \), called the potential, be the solution to the partial differential equation,

\[
\nabla \cdot \sigma \nabla u = 0 \quad \text{in } \Omega \\
\sigma \frac{\partial u}{\partial \nu} = I \quad \text{on } \partial \Omega
\]

\[
\int_{\partial \Omega} u \, dS = 0,
\]

where \( \nu \) is the unit outward normal to \( \partial \Omega \) and \( \frac{\partial u}{\partial \nu} = \nabla u \cdot \nu \). The function \( I \) is restricted to be such that \( \int_{\partial \Omega} I \, dS = 0 \). This Neumann boundary value problem, referred to as the forward problem, has a unique solution \( u \in H^1(\Omega) \) (at least in the weak sense), given that \( I \in H^{-1/2}(\partial \Omega) \) (the potential is unique up to an additive constant, that we fix by imposing the condition \( \int_{\partial \Omega} u \, dS = 0 \)).

The Neumann-to-Dirichlet operator \( \Lambda_\sigma : \{ I \in H^{-1/2}(\partial \Omega), \int_{\partial \Omega} I \, dS = 0 \} \rightarrow H^{1/2}(\partial \Omega) \), maps the Neumann boundary data \( I \) to the restriction (trace) of \( u \) to the boundary of \( \Omega \):

\[
\Lambda_\sigma I = u|_{\partial \Omega}.
\]

This map depends nonlinearly on the conductivity \( \sigma \). The Dirichlet-to-Neumann map can also be considered, \( \Lambda^{-1}_\sigma : H^{1/2}(\partial \Omega) \rightarrow H^{-1/2}(\partial \Omega) \) with \( \Lambda^{-1}_\sigma V = \sigma \frac{\partial u}{\partial \nu} \), where \( u = V \) on \( \partial \Omega \).

1.2 The Inverse Problem

The inverse conductivity problem, as formulated by Calderón [8], is to find a bounded, strictly positive function \( \sigma(x) \), given the map \( \Lambda^{-1}_\sigma \). Theoretically, this problem can be solved uniquely for a large class of functions \( \sigma \), as established in [2], [27], [20], [15], [16], [6], and [23] (we highlight in particular the more recent work [2], in two dimensions, where only the above assumptions on \( \Omega \) and \( \sigma \) are imposed). We will assume knowledge of the \( \Lambda_\sigma \) rather than \( \Lambda^{-1}_\sigma \), since in practice it is less sensitive to noise. Thus, we want to recover a function \( \sigma \in L^\infty(\Omega) \), satisfying \( \sigma(x) \geq \sigma_0 > 0 \) in \( \Omega \), given \( I \) and \( V = u|_{\partial \Omega} \).

We introduce the adjoint potential, \( \tau \), as the unique solution to the following problem (called the adjoint problem),

\[
\nabla \cdot \sigma \nabla \tau = 0 \quad \text{in } \Omega \\
\sigma \frac{\partial \tau}{\partial \nu} = u|_{\partial \Omega} - V \quad \text{on } \partial \Omega
\]

\[
\int_{\partial \Omega} \tau \, dS = 0.
\]
Here \( u \) is the solution to the forward problem (1) and \( V \in H^{1/2}(\partial \Omega) \) is such that \( \int_{\partial \Omega} V \, dS = 0 \). The adjoint potential will be useful in later sections.

### 1.3 Piecewise-constant image segmentation model

Here, we briefly review the piecewise-constant segmentation method, called “active contours without edges”, introduced in [9], [10]. This method will be used to recover the conductivity \( \sigma \) in the next section. Based on the piecewise-constant minimal partition problem of Mumford and Shah [19], the authors in [9], [10] have proposed implicit curve evolution techniques propagating with non-local terms, to solve particular cases of the minimal partition problem. In this problem [19], an image \( f : \Omega \to \mathbb{R} \) is partitioned into several regions \( \Omega_i \), such that the gray-scale level in each \( \Omega_i \) is close to an average constant \( c_i \). This can also be seen as an inverse problem, and can be accomplished by minimizing the energy functional [19],

\[
E^{MS}(\sigma, C) = \lambda \sum_i \int_{\Omega_i} |f(x) - c_i|^2 \, dx + \mu \text{Length}(C),
\]

where \( \mu \) and \( \lambda \) are tuning parameters, \( C \) is a piecewise smooth curve that partitions \( \Omega \) into \( \Omega_i \), and \( \sigma = c_i \) is constant in each \( \Omega_i \). A simple observation shows that for a fixed \( C \), the value of \( c_i \) that minimizes this functional is given by the average of \( f \) over \( \Omega_i \). The function \( \sigma(x) = \sum_i c_i \chi_{\Omega_i}(x) \) will be an “optimal” piecewise-constant approximation of \( f \). In practice, however, it is difficult to minimize the functional (3). For particular cases, when \( \sigma \) takes a finite number of values \( c_i \), the minimal partition problem can be put in the variational level set framework from [31], [22], [13], [14], in the following way [9], [10]. Suppose that we are working in the simplified case of binary segmentation. The image \( f \) can be partitioned using a Lipschitz-continuous function \( \phi \) into two regions, one region where \( \phi > 0 \) and another where \( \phi < 0 \). The zero level-line of \( \phi \) will define the curve \( C = \{ x \in \Omega : \phi(x) = 0 \} \). Thus \( \Omega = \{ \phi(x) > 0 \} \cup \{ \phi(x) < 0 \} \cup \{ \phi(x) = 0 \} \). The length of \( C \) will be given by \( \text{Length}(C) = \int_{\Omega} |\nabla \phi| \, dx = \int_{\Omega} \delta(\phi)|\nabla \phi| \, dx \), where \( \delta \) is the Heaviside function and \( \delta \) is the Dirac delta function. In this case, the functional (3) can be rewritten as [9], [10],

\[
E^{CV}(c_1, c_2, \phi) = \lambda \int_{\Omega} \left[ |f(x) - c_1|^2 H(\phi(x)) + |f(x) - c_2|^2 (1 - H(\phi(x))) \right] \, dx + \mu \int_{\Omega} \delta(\phi)|\nabla \phi| \, dx.
\]

Following the observation from the previous paragraph, the optimal constants \( c_1 \) and \( c_2 \) for a fixed \( \phi \) are given by

\[
c_1 = \frac{\int_{\Omega} f(x) H(\phi(x)) \, dx}{\int_{\Omega} H(\phi(x)) \, dx}, \quad c_2 = \frac{\int_{\Omega} f(x)(1 - H(\phi(x))) \, dx}{\int_{\Omega} (1 - H(\phi(x))) \, dx}.
\]

Introducing an artificial time, \( t \geq 0 \), one verifies that with \( \phi(x, t) \) satisfying

\[
\frac{\partial \phi}{\partial t} = \delta(\phi) \left[ \mu \text{div} \left( \frac{\nabla \phi}{|\nabla \phi|} \right) - \lambda |f - c_1|^2 + \lambda |f - c_2|^2 \right] \quad \text{in} \quad \Omega \quad \text{(5)}
\]

\[
\frac{\partial \phi}{\partial \nu} = 0 \quad \text{on} \quad \partial \Omega, \quad \text{(6)}
\]
$E^{CV}$ will be a non-increasing function of $t$. Extensions to piecewise-constant segmentation with more than two regions and piecewise-smooth segmentation, in a variational multiphase approach, have been introduced in [30]. Related work for region-based segmentation and partitioning was done by [29], [28], [25], together with other references mentioned in [30].

1.4 Related Prior Work

We mention that L. Rondi and F. Santosa have previously applied the Ambrosio-Tortorelli approximations [1] of the general Mumford-Shah problem [19] to the inverse conductivity problem in an elegant work [24], where $\sigma$ is recovered from an energy minimization formulation with data fidelity term and regularizing term. The authors give theoretical results of existence of piecewise-smooth minimizers $\sigma$ in $SBV(\Omega)$, and show convergence of the elliptic approximations by $\Gamma$-convergence. Our proposed computational method is thus different from the method proposed in [24], because we use the level set approach to minimize the Mumford and Shah functional for the simpler (although more restrictive) piecewise-constant binary segmentation case.

Segmentation techniques for recovering the conductivity $\sigma$ and other elliptic equation coefficients have been proposed by T. Chan, E. Chung, and X.C. Tai [11], [12] using approaches similar to the approach in this paper. The work [11] considers a different, but related inverse problem; it applies a slightly modified version of the piecewise-constant segmentation method from [9], [10], [30] to recover the coefficient $q(x)$ from an elliptic PDE, by using the total variation, $\int_{\Omega} |\nabla q| dx$, as a regularization, instead of the length regularization. The work [12] (that much inspired this work) addresses the problem of inverse conductivity; it uses a binary piecewise-constant segmentation method, as in [9], [10], but the regularization is again the total variation. In this work, we show that the length term of the discontinuity set of $\sigma$ is sufficient to recover $\sigma$ with high accuracy and smaller jumps, and is simpler in the piecewise-constant case; also, our computational results need about 200-250 iterations for convergence to steady-state instead of 200 - 50000 iterations in [12]; finally, we also show that interior contours (or holes) of the conductivity $\sigma$ can also be detected by the proposed approach.

The work of L. Borcea et al. [4] also uses a variational approach with regularization to recover the conductivity $\sigma$, but in a different way from the present approach.

Our work was much motivated by all the above-mentioned approaches [24], [11], [12], [4].

Other related work, some very recent, can be found in [26], [18], [17], [21], [7], [4], [3], and [5].

2 Formulation of the Minimization

In practice, we do not completely know the Neumann-to-Dirichlet or Dirichlet-to-Neumann map. Instead, we are given a set of $N$ evaluations of the map. Therefore, we assume that $\Lambda_{\sigma^*}$ is known for $N$ functions for the true conductivity $\sigma^*$. That is, there are $N$ pairs of functions $(I_n, V_n)$ such that $\Lambda_{\sigma^*}I_n = V_n$. Experimentally, this is accomplished by setting a current excitation pattern $I_n$ and measuring the resulting voltage $V_n$ at discrete locations of the electrodes along the boundary $\partial \Omega$. 

In practice, the EIT problem is to find \( \sigma^* \) from partial and usually noisy knowledge of \( \Lambda_{\sigma^*} \). A significant difficulty is the severe ill-posedness of EIT. This problem is ill-posed in the sense that small perturbations of the boundary data are exponentially amplified in the image of \( \sigma \) inside \( \Omega \) \[3\]. Therefore, in the reconstruction process, we have to restrict \( \sigma \) to a subset of \( L^\infty(\Omega) \), of smoother functions, as in \[4\], \[24\], \[11\], \[12\], among others.

In order to obtain a numerical solution to the inverse conductivity problem, we formulate it as a minimization: the functional to be optimized will consist of a data fidelity term (fitting term), and of a regularization term. Using the ideas of the minimal partition problem and piecewise-constant reconstruction \[19\], \[9\], \[10\] in a level set framework, in the simplified case of piecewise constant \( \sigma \), taking two values, we let

\[
\sigma(\phi, c_1, c_2) = c_1 + (c_2 - c_1)H(\phi),
\]

where \( \phi \) is the level set function, \( c_1 \) and \( c_2 \) are the constant values of the conductivity, and \( H \) is the Heaviside function. Therefore, motivated by the classical Mumford and Shah functional \[19\] and its binary level set forms \[9\], \[10\], we minimize the energy functional,

\[
E(\phi, c_1, c_2) = F(\sigma(\phi, c_1, c_2)) + \alpha(F)L(\phi),
\]

where the fitting term and the regularizing length term are given respectively by,

\[
F(\sigma) = \sum_{n=1}^{N} \frac{\|\Lambda_{\sigma^*} I_n - V_n\|_2^2}{N\|V_n\|_2^2},
\]

\[
L(\phi) = \int_{\Omega} |\nabla H(\phi)|dx = \int_{\Omega} \delta(\phi)|\nabla \phi|dx,
\]

with \( \alpha(s) \) a non-decreasing function such that \( \alpha(0) = 0 \). This function allows us to control the size of the regularization. Note that under these restrictions on \( \alpha \), we automatically have that the true conductivity \( \sigma^* = \sigma(\phi^*, c_1^*, c_2^*) \) is an absolute minimum of the functional, as \( E(\phi^*, c_1^*, c_2^*) = 0 \) (at least in the noiseless case).

By this minimization, we have that \( \sigma \in SBV(\Omega) \) (\( \sigma \) will be a piecewise-constant function, with the discontinuity set of finite length).

We now introduce an artificial time parameter \( t \) and let \( \phi(\cdot) = \phi(\cdot, t), c_1 = c_1(t) \) and \( c_2 = c_2(t) \). Differentiating the energy, we obtain:

\[
\frac{dE}{dt} = \frac{\partial E}{\partial c_1} \frac{dc_1}{dt} + \frac{\partial E}{\partial c_2} \frac{dc_2}{dt} + \int_{\Omega} \frac{\partial E}{\partial \phi} \frac{d\phi}{dt} dx.
\]

Furthermore,

\[
\frac{\partial E}{\partial \phi} = (1 + \alpha'(F)L)\frac{\partial F}{\partial \phi} + \alpha(F)\frac{\partial L}{\partial \phi} = (1 + \alpha'(F)L)\frac{\partial F}{\partial \sigma} \frac{\partial \sigma}{\partial \phi} - \alpha(F)\delta(\phi)\nabla \cdot \nabla \phi
\]

\[= \delta(\phi)\left((1 + \alpha'(F)L)(c_2 - c_1)\frac{\partial F}{\partial \sigma} - \alpha(F)\nabla \cdot \frac{\nabla \phi}{|\nabla \phi|}\right),\]
and
\[
\frac{\partial E}{\partial c_1} = (1 + \alpha'(F)L) \int_{\Omega} \frac{\partial F}{\partial \sigma} \frac{\partial \sigma}{\partial c_1} dx
\]
\[
= (1 + \alpha'(F)L) \int_{\Omega} \frac{\partial F}{\partial \sigma} (1 - H(\phi)) dx.
\]
Similarly,
\[
\frac{\partial E}{\partial c_2} = (1 + \alpha'(F)L) \int_{\Omega} \frac{\partial F}{\partial \sigma} H(\phi) dx.
\]

Let \(u_n\) and \(\tau_n\) the \(n^{th}\) potential and adjoint potential, so that they respectively solve (1) and (2) with \(I = I_n\) and \(V = V_n\). It can be shown that the Fréchet derivative of the fitting term is given by (see for example [4] or [12]),
\[
\frac{\partial F}{\partial \sigma} = -2 \sum_{n=1}^{N} \nabla u_n \cdot \nabla \tau_n \frac{\nabla}{\nabla \phi} \frac{1}{N\|V_n\|^2}.
\]

Thus if we set,
\[
\frac{d\phi}{dt} = -\delta(\phi) \left( (1 + \alpha'(F)L)(c_2 - c_1) \frac{\partial F}{\partial \sigma} - \alpha(F) \nabla \cdot \nabla \phi \right),
\]
\[
\frac{dc_1}{dt} = -(1 + \alpha'(F)L) \int_{\Omega} \frac{\partial F}{\partial \sigma} (1 - H(\phi)) \, dx,
\]
\[
\frac{dc_2}{dt} = -(1 + \alpha'(F)L) \int_{\Omega} \frac{\partial F}{\partial \sigma} H(\phi) \, dx,
\]
we have that \(\frac{dE}{dt} \leq 0\). Hence, these equations give the minimization formulation of the inverse conductivity problem.

3 Numerical details and reconstruction results

In the following numerical experiments, we take the domain to be the unit square, \(\Omega = [0, 1]^2\). To derive the linear system of equations that represents \(\nabla \cdot \sigma \nabla\) at the grid points away from the boundary, we look at the integral of equation (1) (or (2)) over a square, \(P\), centered at a grid point (see Figure 1):

![Integration domains](image.png)

Figure 1: Integration domains.
\[
0 = \int_p \nabla \cdot \sigma \nabla u \, dx = \int_{\partial p} \sigma \frac{\partial u}{\partial n} \, dS.
\]

Using finite differences to approximate the normal derivative of \(u\) in this formula, we obtain:

\[
0 = \sigma_{i,j} \left( \frac{u_{i+1,j} - u_{i,j}}{h} \right) + \sigma_{i,j-1} \left( \frac{u_{i,j-1} - u_{i,j}}{h} \right)
+ f_{i,j} + \frac{\sigma_{i-1,j} + \sigma_{i+1,j} + \sigma_{i,j-1} + \sigma_{i,j+1}}{h^2} u_{i,j},
\]

At the boundary nodes, but not the corner nodes, we use the boundary condition,

\[
\sigma \frac{\partial u}{\partial n} = f,
\]

where \(f\) is either \(I\) or \(u|_{\partial \Omega} - V\), and we integrate over a domain, \(Q\), (see Figure 1):

\[
0 = \int_Q \nabla \cdot \sigma \nabla u \, dx = \int_{\partial Q} \sigma \frac{\partial u}{\partial n} \, dS
= \sigma_{i,j} \left( \frac{u_{i+1,j} - u_{i,j}}{h} \right) + \sigma_{i,j-1} \left( \frac{u_{i,j-1} - u_{i,j}}{h} \right)
+ f_{i,j} + \frac{\sigma_{i-1,j} + \sigma_{i+1,j} + \sigma_{i,j-1} + \sigma_{i,j+1}}{h^2} u_{i,j},
\]

In a similar fashion, we obtain the equations at the four corner nodes. Note that in this discretization of the operator, we need the values of the conductivity at points which lie in between the grid points. We take its value to be the minimum of the two nearest values to preserve the discontinuous nature of \(\sigma\). This approximation ignores isolated points, where \(\sigma\) is bigger than at its surrounding neighbors. This is taken into consideration in evaluating \(dc/dt\) and in re-normalizing \(\phi\).

We will assume that the conductivity constant \(c_1 = 1\) is fixed and that it is the value of \(\sigma^*\) on the boundary of the domain. In this case, the evolution equations for \(\phi\) and the unknown conductivity constant \(c_2 = c\) are given by:

\[
\frac{d\phi}{dt} = -\delta(\phi) \left( (1 + \alpha'(F))(c - 1) \frac{\partial F}{\partial \sigma} - \alpha(F) \nabla \cdot \frac{\nabla \phi}{|\nabla \phi|} \right), \quad (7)
\]

\[
\frac{dc}{dt} = -(1 + \alpha'(F)L) \int_{\Omega} \frac{\partial F}{\partial \sigma} H(\phi) \, dx. \quad (8)
\]

Following [10], we use a semi-implicit finite-difference scheme to discretize the \(\nabla \cdot \frac{\nabla \phi}{|\nabla \phi|}\) term. Since we are assuming that one of the values of the conductivity is known, we impose Dirichlet boundary conditions on \(\phi\). We use the approximations of the Heaviside and Dirac delta functions given in [9], [10],

\[
H_\epsilon(x) = \frac{1}{2} \left[ 1 + \frac{2}{\pi} \arctan \left( \frac{x}{\epsilon} \right) \right], \quad \delta_\epsilon(x) = \frac{1}{\pi \epsilon^2 + x^2}.
\]
To compute the Fréchet derivative of the fitting term, we need the potential and the adjoint potential in $\Omega$ for each one of the configurations. To find these potentials, we use the conjugate gradient method to solve the system of linear equations that results from the finite volume discretization of (1) and (2). In discretizing the $\nabla \cdot \sigma \nabla \phi$ operator, we also use the above approximations, $H_\epsilon$ and $\delta_\epsilon$. However, since the finite volume discretization requires the values of $\sigma$ at the half grid points, we take its value to be the minimum of the two nearest values to preserve the discontinuous nature of $\sigma$, as explained before.

Since there is no analytic solution to the equation that governs the evolution of $c$, the differential equation (8) has to be solved numerically. However, instead of integrating this equation, we evaluate $\frac{dc}{dt}$ nearby the previous value of $c$ and approximate $\frac{dc}{dt}$ by a quadratic polynomial. The next value of $c$ is taken to be the value that minimizes the absolute value of this polynomial (if there are two such points, we take the one closest to the previous value). We alternate minimizing the functional with respect to $\phi$ and $c$.

To generate artificial data, we compute the Neumann-to-Dirichlet map, $\Lambda_{\sigma^*}$, by applying the conjugate gradient method to the finite volume discretization of the forward problem. The Neumann boundary data are chosen to be sines and cosines of higher and higher frequency on the boundary.

For the cases with regularizations, we use
\[ \alpha(F) = 10^{-7} \frac{\pi}{\arctan(10^7 F)}, \]
and for no regularization, we use $\alpha(F) = 0$.

### 3.1 Test 1 – Two Inclusions

The true conductivity for this experiment has two inclusions (see Figure 2). Both inclusions have conductivity $c_2^* = 2$ and the background conductivity $c_1^* = 1$. The reconstructions in Figure 4 were carried out using 6 configurations both with regularization and without regularization. Figure 5 shows the same reconstructions using 12 configurations. We also show the value of the fidelity term $F(t)$ versus iteration number. The overall behavior of the total energy $E(t)$ is qualitatively very similar to the behavior of the fidelity term. The final values from the minimization are listed in Table 1.

3.3 Test 3 – Noise

For this experiment, we use the true conductivity $\sigma_1^*$ of test 1. However, the measurements $V_n$ are corrupted with additive uniformly distributed noise, that is,

$$V_n^\text{c} = (1 + \epsilon_n) V_n,$$

where $\epsilon_n$ is a uniformly distributed noise.
where \( s_n \) is a function on the boundary of \( \Omega \) that takes on random values between \([-1, 1]\) and \( \epsilon \) controls the size of noise. Figure 9 shows regularized reconstructions of \( \sigma^*_1 \) with \( N = 12 \) and noisy data with \( \epsilon = .01 \) and \( \epsilon = .05 \), while the final values are given in Table 3.
